# Homework Assignments

Homework assignment #3

Chapter Four

Due by May 22.....

# Multicast: one sender to many receivers

- **Multicast:** act of sending datagram to multiple receivers with single “transmit” operation
  - analogy: one teacher to many students

# Uses of Multicasting

- Multimedia “broadcast”: IP radio, webcasts
- Teleconferencing: multiparty videoconferencing with (Mbone, CUSeeMe)
- Database replication
- Distributed computing: immediate updates to all members
- Real-time workgroups: multimedia collaboration
- System management: concerted file updates to group of hosts
- Stock ticker: low-bandwidth quotes to millions of hosts (cf. Pointcast)

# **Multicast: one sender to many receivers**

**Question:** how to achieve multicast

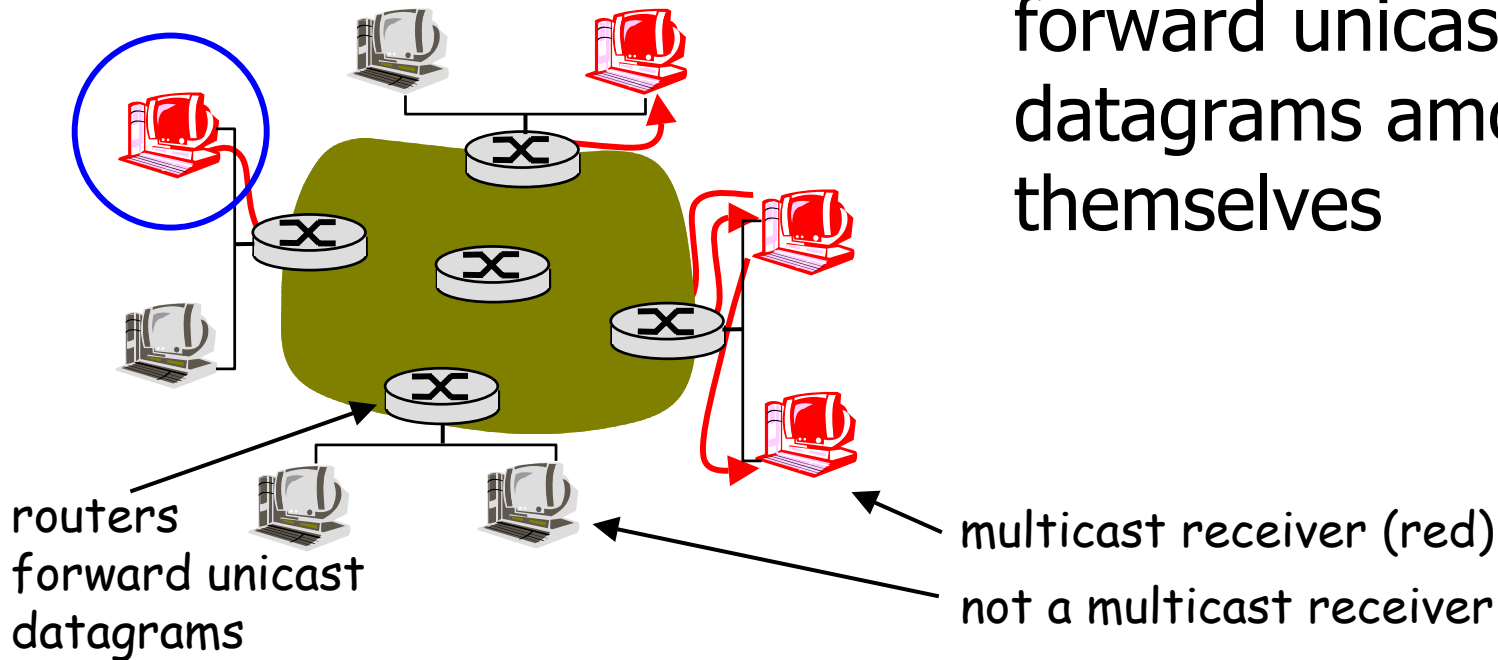

# Multicast via Unicast

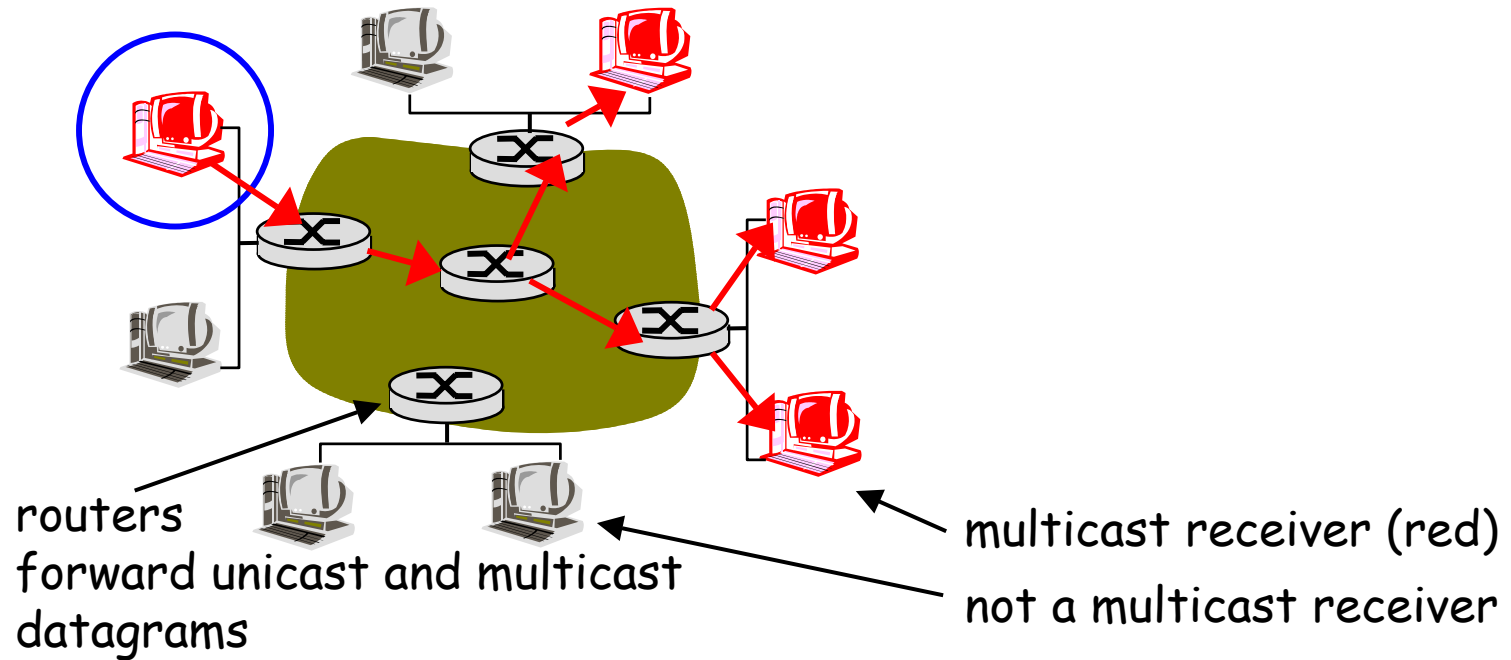

source sends  $N$  unicast datagrams, one addressed to each of  $N$  receivers

# Application Layer Multicast

- end systems involved in multicast copy and forward unicast datagrams among themselves

# Network Multicast

# Tunneling

**Q:** How to connect “islands” of multicast routers in a “sea” of unicast routers?

physical topology

logical topology

- ❑ mcast datagram encapsulated inside “normal” (non-multicast-addressed) datagram
- ❑ normal IP datagram sent thru “tunnel” via regular IP unicast to receiving mcast router
- ❑ receiving mcast router unencapsulates to get mcast datagram

# IP Multicast Architecture

- Based on Steve Deering's original proposal (SIGCOMM 88 Proceedings; his PhD thesis)
- It consists of three basic components:
  - Group addressing based on **globally unique identifiers** (IP multicast addresses)
  - Separation of senders and receivers with **anonymous receiver affiliation**
  - A **tree-based routing and group structure**

# IP Multicast Architecture (contd..)

multicast group concept: use of **indirection**

- ▣ hosts addresses IP datagram to multicast group
- ▣ routers forward multicast datagrams to hosts that have "joined" that multicast group

# IP Multicast Addresses

- 28 bits for groups ~ 250 million groups
- **Two kinds of supported addresses:**
  - **Permanent**, e.g.,
    - 224.0.0.1 all systems on LAN
    - 224.0.0.2 all routers on LAN
  - **Temporary - must be created before they can be addressed (join and leave)**

# IP Multicast Addressing Problem

- There are plenty of IPv4 and IPv6 addresses for globally unique multicast addresses!
- **The problem is how to assign these addresses permanently or temporarily to multicast groups.**
- **Using globally unique multicast addresses requires Internet-wide coordination in the assignment of identifiers to groups!**
- **Evolving solution: Make multicast identifiers locally unique; examples are now evolving**
  - (e.g., EXPRESS, Simple Multicast use the IP address of a core and a multicast address that the core uses for only one group as the identifier of a group).

# IGMP: Internet Group Management Protocol

- host: sends IGMP report when application joins mcast group
- router: sends IGMP query at regular intervals
  - ▣ host belonging to a mcast group must reply to query

# Joining a mcast group: two-step process

# Per Source Per Group Tree

# Shortest Path Tree

- Multicast forwarding tree: tree of shortest path routes from source to all receivers
  - ▣ Dijkstra's algorithm

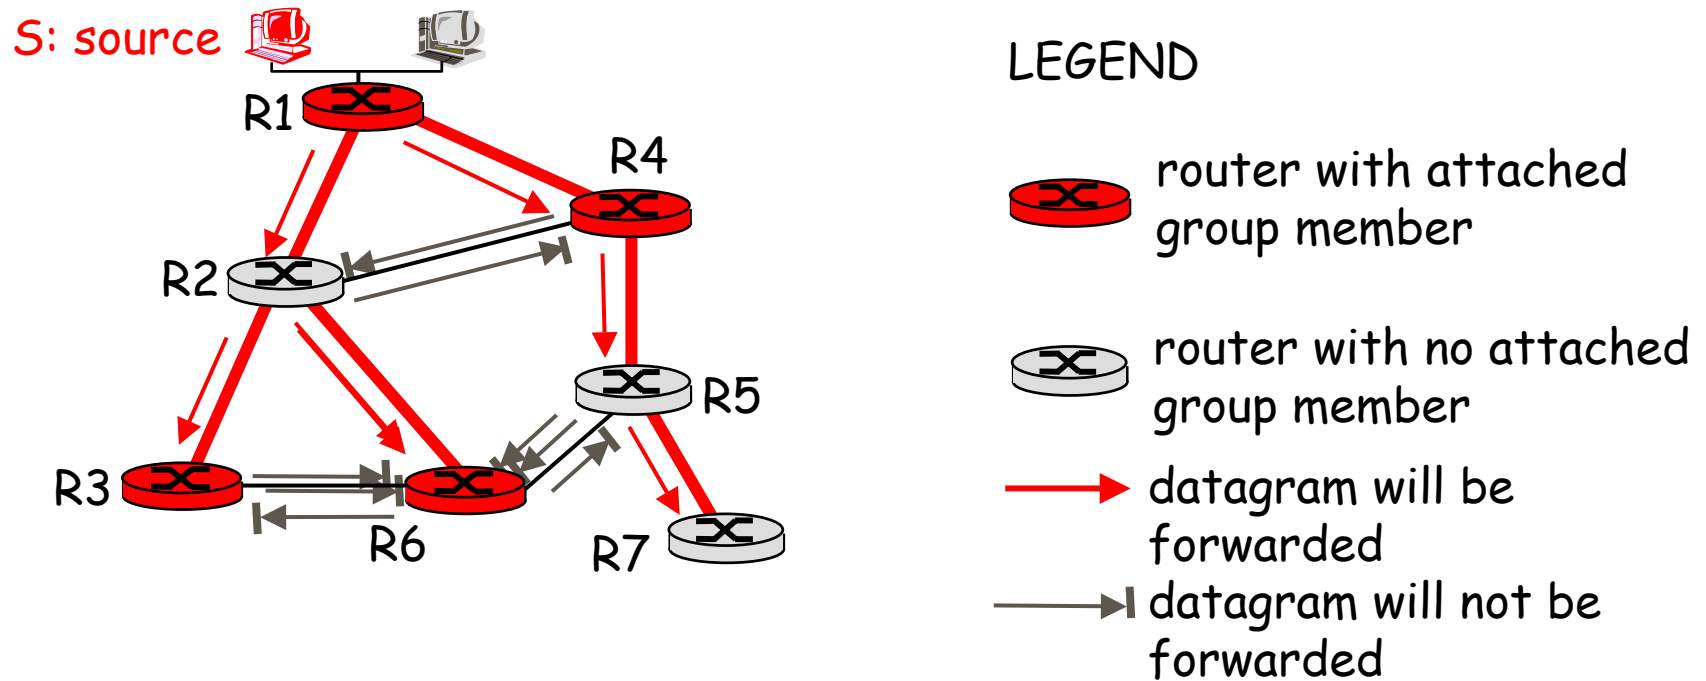

# Reverse Path Forwarding

- rely on router's knowledge of unicast shortest path from it to sender
- each router has simple forwarding behavior:

*if* (mcast datagram received on incoming link on shortest path back to center)  
*then* flood datagram onto all outgoing links  
*else* ignore datagram

# Reverse Path Forwarding: example

- result is a source-specific *reverse* SPT
  - may be a bad choice with asymmetric links

# Reverse Path Forwarding: pruning

- “prune” msgs sent upstream by router with no downstream group members

# Distance Vector Multicast Routing Protocol (DVMRP)

- **DVMRP**: distance vector multicast routing protocol, RFC1075
- *flood and prune*: reverse path forwarding, source-based tree
  - ▣ RPF tree based on DVMRP's own routing tables constructed by communicating DVMRP routers
  - ▣ no assumptions about underlying unicast
- odds and ends
  - ▣ commonly implemented in commercial routers
  - ▣ Mbone routing done using DVMRP

# Problems with Basic Approach

- Flooding the Internet to establish a multicast routing tree is not an option!
- This is the key reason why multicasting (based on DVMRP) cannot be deployed on a large scale.
- The problem stems from the lack of addressing information in an IP multicast address!
- **Where is a multicast group on the Internet?**
- **The solution to this problem is to use special nodes as the “address” of a group**

# Per Group Shared Tree

# Shared Tree

Shared tree

# Shared-Tree: Steiner Tree

- **Steiner Tree:** minimum cost tree connecting all routers with attached group members
- Problem is NP-complete, heuristics exists
- Not used in practice:
  - Computational complexity
  - Information about entire network needed
  - Monolithic: rerun whenever a router needs to join/leave

# Center-based trees

- single delivery tree shared by all
- one router identified as "*center*" of tree
- to join:
  - edge router sends unicast *join-msg* addressed to center router
  - *join-msg* "processed" by intermediate routers and forwarded towards center
  - *join-msg* either hits existing tree branch for this center, or arrives at center
  - path taken by *join-msg* becomes new branch of tree for this router

# Center-based trees: an example

Suppose R6 chosen as center:

## LEGEND

-  router with attached group member
-  router with no attached group member
-  path order in which join messages generated

# PIM: Protocol Independent Multicast

- not dependent on any specific underlying unicast routing algorithm (works with all)
- two different multicast distribution scenarios :

## Dense:

- group members densely packed, in "close" proximity.
- bandwidth more plentiful

## Sparse:

- # networks with group members small wrt # interconnected networks
- group members "widely dispersed"
- bandwidth not plentiful

# Consequences of Sparse-Dense Dichotomy:

## Dense

- group membership by routers *assumed* until routers explicitly prune
- *data-driven* construction on mcast tree (e.g., RPF)
- bandwidth and non-group-router processing *profligate*

## Sparse:

- no membership until routers explicitly join
- *receiver-driven* construction of mcast tree (e.g., center-based)
- bandwidth and non-group-router processing *conservative*

# PIM- Dense Mode

**flood-and-prune RPF**, similar to DVMRP but

- ❑ underlying unicast protocol provides RPF info for incoming datagram
- ❑ less complicated (less efficient) downstream flood than DVMRP reduces reliance on underlying routing algorithm
- ❑ has protocol mechanism for router to detect it is a leaf-node router

# PIM - Sparse Mode

- Center (core)-based approach
- router sends *join* msg to rendezvous point (RP)
  - intermediate routers update state and forward *join*
- after joining via RP, router can switch to source-specific tree
  - increased performance: less concentration, shorter paths

# PIM - Sparse Mode

sender(s):

- unicast data to RP, which distributes down RP-rooted tree
- RP can extend mcast tree upstream to source
- RP can send *stop* msg if no attached receivers
  - “no one is listening!”
