\textbf{printf()}

Standard Library Function

- Used to write text to the "standard output"
- Normally a computer monitor or printer
- Often the UART in embedded systems
- SIM Uart1/2 window in MPLAB X
printf() Standard Library Function

Syntax

```c
printf(ControlString, arg1, ..., argn);
```

- Everything printed verbatim within string except %d's which are replaced by the argument values from the list.

Example

```c
int a = 5, b = 10;
printf("a = %d\n b = %d\n", a, b);
```

Result:

```
a = 5
b = 10
```

NOTE: the 'd' in %d is the conversion character.
(See next slide for details)
The value displayed is interpreted entirely by the formatting string:

```c
printf("ASCII = %d", 'a');
```

will output: `ASCII = 97`

A more problematic string:

```c
printf("Value = %d", 6.02e23);
```

will output: `Value = 26366`

Incorrect results may be displayed if the format type doesn't match the actual data type of the argument.
printf() operates on lines of text.

Output text may not be transmitted until a newline is sent.

Example

```c
printf("a");
```

Output:
printf()  
Output buffer

- printf() operates on lines of text.
- Output stored in a buffer until a newline triggers transmission.

**Example**

```c
printf("a\n");
```

Output:

```
"a\n"
```
printf()

The output buffer

stdio.h

output buffer

UART
printf()  
Format specifiers  

%[flags][width][.precision][size]type  
• Flags – Special printing options  
• Width – The minimum size (in chars) of the output  
• Precision – Field width  
• Size – Convert from base types to longer/shorter types  
• Type – The base variable type
printf()
Format specifiers

%[flags][width][.precision][size]type

- **Flags** – Special printing options
  - ‘-‘ -> Left justify
  - ‘0’ -> Pad with zeros
  - ‘+’ -> Output ‘+’ for positive values
  - ‘ ‘ -> Don’t output a sign symbol
  - ‘#’ -> Prefix integer value based on output type

\[0, +1\quad -4\quad -4\]
\[+4\quad 4\]
Port 2 <
Port 1 - 4FEB ... <

Lab 1
Lab 2
Lab 3

# include "..\common\h"

common board < h
`printf()`

Format specifiers

`%[flags][width][.precision][size]type`

- **Width** – The minimum size (in chars) of the output
  - Output is padded
  - ‘0’ flag specifies padding with ‘0’s instead of ‘ ‘s
printf() 
Format specifiers

%[flags][width][.precision][size]type

• Precision – Field width
  – For integers, minimum number of digits
  – For floats, number of fractional digits/significant figures
  – For strings, number of characters
printf()
Format specifiers

%[flags][width][.precision][size]type

- **Size** – Convert from base types to longer/shorter types
  - ‘h’ -> Converts to short
  - ‘l’ -> Converts to long/double
  - ‘ll’ -> Converts to long long/long double
# printf()

Format specifiers

<table>
<thead>
<tr>
<th>Conversion Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Single character</td>
</tr>
<tr>
<td>s</td>
<td>String (all characters until '\0')</td>
</tr>
<tr>
<td>d</td>
<td>Signed decimal integer</td>
</tr>
<tr>
<td>o</td>
<td>Unsigned octal integer</td>
</tr>
<tr>
<td>u</td>
<td>Unsigned decimal integer</td>
</tr>
<tr>
<td>x</td>
<td>Unsigned hexadecimal integer with lowercase digits (1a5e)</td>
</tr>
<tr>
<td>X</td>
<td>As x, but with uppercase digits (e.g. 1A5E)</td>

<tr>
<td>f</td>
<td>Signed decimal value (floating point)</td>
</tr>
<tr>
<td>e/E</td>
<td>Signed decimal with exponent (e.g. 1.26e-5)</td>
</tr>
<tr>
<td>p</td>
<td>A pointer value indicating a memory address</td>
</tr>
<tr>
<td>g/G</td>
<td>As e or f, but depends on size and precision of value</td>
</tr>
<tr>
<td>g</td>
<td>Prints ‘%’</td>
</tr>
</tbody>
</table>

Maxwell James Dunne
printf()  
Format String Examples

• Print a hexadecimal:

```c
printf("0x%06x\n", x);
```

0  Any unused spaces will be filled with zeros

6  Specifies that 6 characters must be output (including 0x prefix)
printf()  
Format String Examples

• Printing a double:

```c
printf("f = 806.3f\n", f);
```

0  Any unused spaces will be filled with zeros
6  Specifies that 6 characters must be output
.3  Specifies that 3 decimal places will be output

3.3  123456
     03.300
printf()  
Format String Examples

• Printing a double:

```c
printf("%.1f88\n", percentCorrect);
```

.1  Specifies that 1 decimal place will be output

%%  Outputs a literal ‘%’
printf()  
Format String Examples

• Printing a double:

```c
printf("%lf\n", (double)percentCorrect);
```

.1  Specifies that 1 decimal place will be output

%%  Outputs a literal ‘%’

97.322  97.38
Print("cat")

scanf()  
Standard Library Function  

• Used to read input from the "standard input"  
• Normally a keyboard or file  
• Often the UART in embedded systems  
• Input file in the simulator  
• Entire family of functions:  
  – sscanf() reads from a string  
  – fscanf() reads from a file
`scanf()`
Standard Library Function

Syntax

```c
int scanf(FormatString, arg1, ..., argn);
```

- The format string tells `scanf` what kind of input.
- `arg1` through `argn` are **POINTERS** to variable of the right type.

Example

```c
int a, b;
printf("Input a and b\n");
scanf("%d %d", &a, &b);
printf("a=%d\n b=%d", a, b);
```
scanf()

Gotchas

- Ignores blanks and tabs in format string
- Skips over white space (blanks, tabs, newline) as it looks for input
- Returns number of successful conversions
- Arguments **must** be pointers to variable types
- Arguments not processed in the input will be left in the input buffer.
`scanf()`

The input buffer

`stdio.h`

output buffer

Input buffer

UART
`scanf()`
Standard Library Function

Example

```c
int a, b;
printf("Input a and b\n");
scanf("%d %d", &a, &b);
printf("a=%d\nb=%d", a, b); ← "3140 56\n"
scanf("%d %d", &a, &b);
printf("a=%d\nb=%d", a, b); ← "77 -3\n"
```
`scanf()`

The input buffer

```
3 1 4 0 5 6 \n
```

`scanf("%d %d", &a, &b)`

```
3 1 4 0 5 6 \n
```

a = 3140, b = 56
**scanf()**

The input buffer

```
\n7 7 - 3 \n```

\[\text{scanf(\"%d %d\", \&a, \&b)}\]

Nothing!

\[\text{flush}\]
```c
scanf("%d %d%c", &a, &b, &c)
```

The input buffer

```
3 1 4 0 5 6 \n
garbage
```

```
a = 3140, b = 56
```
\texttt{scanf()} \\
Format specifiers

\texttt{%[\texttt{*}][width][modifier]\texttt{type}}

- \texttt{*} – Ignores this field
- Width – The maximum number of characters to match
- Modifier – Convert from base types to longer/shorter types
- Type – The base variable type
**scanf()**

Examples

- Read input line with date in the format:
  - 25/12/2012

```
scanf("%d/%d/%d", &day, &month, &year);
```

day    int, &day is pointer to day

month  int, &month is pointer to month

year   int, &year is pointer to year
**scanf()**

Examples

- Read input line with date in the format:
  - "25 Dec 2012"

```c
scanf("%d %s %d", &day, month, &year);
```

- **day** int, &day is pointer to day
- **month** char[20], is a string for putting the month into, does not need "&" because name of array is already a pointer
- **year** int, &year is pointer to year
the cat does
0% < 0%

the car does
0% > 0%
scanf()

Return value

**Example**

```c
int a, b;
char c;
while (scanf("%d %d%c", &a, &b, &c) != 3) {
    printf("Please enter an integer pair!\n");
}
```

foo
**Arrays**

Arrays are variables that can store many items of the same type. The individual items known as **elements**, are stored sequentially and are uniquely identified by the array **index** (sometimes called a subscript).

- Arrays:
  - May contain any number of elements
  - Elements must be of the same type
  - The index is zero based
  - Array size (number of elements) must be specified at declaration
Arrays
How to Create an Array

Arrays are declared much like ordinary variables:

**Syntax**

```
type arrayName[size];
```

- `size` refers to the number of elements
- `size` can be a constant OR specified at runtime (c99)

**Example**

```c
int a[10];
char s[25];
char str[x];
```
Arrays

How to Initialize an Array at Declaration

Arrays may be initialized with a list when declared:

**Syntax**

```
type arrayName[size] = {item_1, ..., item_n};
```

- The items must all match the *type* of the array

**Example**

```c
int a[5] = {10, 20, 30, 40, 50};

char b[5] = {'a', 'b', 'c', 'd', 'e'};
```
Arrays
How to Use an Array

Arrays are accessed like variables, but with an index:

**Syntax**

```c
arrayName[index]
```

- `index` may be a variable or a constant
- The first element in the array has an index of `0`
- C does not provide any bounds checking

**Example**

```c
int i, a[10]; // An array that can hold 10 integers

for(i = 0; i < 10; i++) {
    a[i] = 0; // Initialize all array elements to 0
}

a[4] = 42; // Set fifth element to 42
```
Arrays
Creating Multidimensional Arrays

Add additional dimensions to an array declaration:

Syntax

```
:type arrayName[size1]...[size_n];
```

- Arrays may have any number of dimensions
- Three dimensions tend to be the largest used in common practice

Example

```
int a[10][10];    // 10x10 array for 100 integers
float b[10][10][10];    // 10x10x10 array for 1000 floats
```
Arrays

Initializing Multidimensional Arrays at Declaration

Arrays may be initialized with lists within a list:

Syntax

type arrayName[size_0]...[size_n] =

{{item,...,item},
 {item,...,item}];

Example

char a[3][3] = {{'X', '0', 'X'},
 {'0', '0', 'X'},
 {'X', 'X', '0'}};

int b[2][2][2] = {{0, 1},{2, 3}},{4, 5},{6, 7}};
Arrays

Visualizing 2-Dimensional Arrays

int a[3][3] = {{0, 1, 2},
               {3, 4, 5},
               {6, 7, 8}};

a[y][x]

Row 0
a[0][0] = 0;
a[0][1] = 1;
a[0][2] = 2;

Row 1
a[1][0] = 3;
a[1][1] = 4;
a[1][2] = 5;

Row 2
a[2][0] = 6;
a[2][1] = 7;
a[2][2] = 8;
Arrays

Visualizing 3-Dimensional Arrays

```c
int a[2][2][2] = {
    {{0, 1}, {2, 3}},
    {{4, 5}, {6, 7}}
};
```

Plane, Row, Column

```c
int a[z][y][x] = {
    a[0][0][0] = 0;
    a[0][0][1] = 1;
    a[0][1][0] = 2;
    a[0][1][1] = 3;
    a[1][0][0] = 4;
    a[1][0][1] = 5;
    a[1][1][0] = 6;
    a[1][1][1] = 7;
};
```
# Arrays

**Example of Array Processing**

```c
/*****************************/
 * Print out 0 to 90 in increments of 10
 *****************************/

int main(void)
{
    int i = 0;
    int a[10] = {0, 1, 2, 3, 4, 5, 6, 7, 8, 9};

    while (i < 10) {
        a[i] *= 10;
        printf("%d\n", a[i]);
        ++i;
    }

    while (1);
}
```
