CMPE 117

Lectures:
Periodic Task Scheduling
© Luca de Alfaro, 2002-3

Quality of schedule

- Response time $R_{ij} = f_{ij} - r_{ij}$
- Critical instant: the time at which, if a task is released, it will have the largest response time.
- Absolute jitter:
  - Start: $\max_j (s_{ij} - r_{ij}) - \min_j (s_{ij} - r_{ij})$
  - Finish: $\max_j (f_{ij} - r_{ij}) - \min_j (f_{ij} - r_{ij})$

Assumptions

- A1: The tasks are periodic, period = $T_i$
- A2: All instances have the same worst-case execution time $C_i$
- A3: All instances have the same relative deadline $D_i = T_i$
- A4: All tasks in the set $I$ of tasks are independent
  (We will relax these conditions later)

More assumptions

- The tasks do not suspend themselves on I/O
- All overheads in the kernel are assumed to be 0.
Processor Utilization

- Processor utilization
  \[ U = \sum_{i=1}^{n} \frac{C_i}{T_i} \]

- For a set of periods \( \Theta \) and an algorithm \( A \), let \( U_{ub}(\Theta, A) \) be the upper bound of the processor utilization factor for tasks with \( \Theta \) to be schedulable by \( A \).
- Let \( U_{lb} = \min_u U_{ub}(\Theta, A) \)
- If \( U \cdot U_{lb} \), we know that the tasks are schedulable!

Critical Instant for RM

The critical instant occurs when all the tasks are released simultaneously.

Task deadlines equal to the period

Worst-Case Response Time for RM

The worst-case response time for a job occurs when it is released simultaneously with all higher-priority (shorter-period) jobs.
The worst-case response time can be computed either from a schedule (as above), or with an equation we will present later.

Rate Monotonic Scheduling

- Assign priority to process \( i \) proportional to the rate \( 1/T_i \)
- Summary:
  - Optimal with respect to all fixed-priority algorithms
  - \( n \) tasks are guaranteed schedulable if \( U \leq n(2^{2i} - 1) \).
  - For \( n \to \infty \), \( n(2^{2i} - 1) \to \ln 2 \approx 0.69 \)

Schedulability test for RM

- Approximate: \( n \) tasks are guaranteed schedulable if \( U \leq n(2^{2i} - 1) \).
- Precise: \( n \) tasks are guaranteed schedulable iff, for all \( 1 \leq i \leq n \), we have \( R_i \leq T_i \), where \( R_i \) is the worst-case response time.
RM is optimal among fixed priority schedulers

- We study the case of two processes, with $T_1 < T_2$.
- RM assigns $P_1 > P_2$.
- We will show this is better than $P_2 > P_1$.
- Clearly, if a generic algorithm uses a different order than RM, there must be at least two processes that are assigned priorities in reverse order wrt. RM.

**Analysis**

- By non-RM: $C_1 + C_2 \leq T_1$ \hspace{1cm} (1)
- By RM: $(F+1)C_1 + C_2 \leq T_2$ \hspace{1cm} (2)
- We show (1) implies (2): rewriting (1),
  
  $$FC_1 + FC_2 \leq F T_1$$  
  $$FC_1 + C_2 \leq F C_1 + FC_2 \leq F T_1$$  
  $$(F+1)C_1 + C_2 \leq F T_1 + C_1$$  
  $$(F+1)C_1 + C_2 \leq F T_1 + C_1 \leq T_2$$

Priority $P_2 > P_1$: (≠ RM)

- Maximum utilization: $C_1 + C_2 \leq T_1$

**Priority $P_2 > P_1$: (≠ RM)**

Priority $P_2 < P_1$: (= RM)

- Case 2: $F = \lfloor T_2 / T_1 \rfloor$, $C_1 \geq T_2 - F T_1$
- Schedulable if $FC_1 + C_2 \leq F T_1$

**Analysis**

- By non-RM: $C_1 + C_2 \leq T_1$ \hspace{1cm} (1)
- By RM: $FC_1 + C_2 \leq F T_1$ \hspace{1cm} (3)
- We show (1) implies (3): rewriting (1),
  
  $$FC_1 + FC_2 \leq F T_1$$  
  $$FC_1 + C_2 \leq FC_1 + FC_2 \leq F T_1$$
Least upper bound for RM

- \( n \) processes sharing CPU: \( n(2^{\ln - 1}) \)
- When \( n \to \infty \): In 2 \( \approx 0.69 \)
- Calculus check:
  \[
  n \left( 2^{\ln} - 1 \right) \\
  = n \left( e^{\ln 2} - 1 \right) \\
  \approx n \left( 1 + (\ln 2)/n - 1 \right) \\
  \approx \ln 2 \text{ as } n \to \infty
  \]

Proof: if not schedulable, then \( \sum_{i=1}^{n} \frac{C_i}{T_i} > 1 \)

Earliest Deadline First

Theorem: A set \( \{\tau_1, \ldots, \tau_n\} \) of periodic tasks is schedulable with EDF iff

\[
\sum_{i=1}^{n} \frac{C_i}{T_i} \leq 1.
\]

Proof: only if: obvious.

Proof: if \( \sum_{i=1}^{n} \frac{C_i}{T_i} \leq 1 \) then schedulable

- We prove: if not schedulable, then \( \sum_{i=1}^{n} \frac{C_i}{T_i} > 1 \)

Schedulability test for EDF

- Precise: \( n \) tasks are guaranteed schedulable if \( U \leq 1 \).

Note: we cannot possibly do better than EDF! So why is RM used? Because it’s simpler: we don’t need to tell the processor the deadlines. It relies on simpler processor scheduling mechanisms.
**DM: Schedulability analysis**

- Naive approach: reduce the problem to RM, and check
  \[ \sum_{i=1}^{n} \frac{C_i}{D_i} \leq n\left(2^{1/n} - 1\right) \]
  
  **Note:** used to be \(T_i\)

But we can do better!

---

### Task deadlines shorter than the period

---

### Periodic tasks with deadlines shorter than the period

Two approaches:

- Deadline monotonic (DM), derived from rate monotonic.
- EDF.
  
  As usual, EDF is optimal.

---

### Deadline Monotonic (DM)

- \(D_i\): deadline of task \(i\), relative to period: \(D_i < T_i\)
- Deadline monotonic algorithm: assign highest priority to the process with the smallest relative deadline \(D_i\).

---

### DM: Schedulability Analysis

Schedulable iff \(R_i \leq D_i\) for all tasks \(J_i\), where \(R_i\) is the worst-case response time.

---

### DM: Schedulability Analysis

How can we compute the worst-case response time?

**Method 1:** by drawing a schedule when all processes are released simultaneously.
Computing the Response Time

We can write the worst-case response time as

\[ R_i = C_i + I_i \]

where \( R_i \) is the response time, and \( I_i \) is the interference to task \( i \) due to tasks having priorities higher than that of \( i \).

---

DM: Schedulability test

\[ R_i = C_i + \frac{1}{\sum_{j=1}^{i-1} \left( R_j / T_j \right)} C_j \]

- We want the least fixpoint.
- Think of it as \( R_i = F(R_i) \).
- Note that \( F \) is monotonic and left-continuous.
- Solution: \( R_i = \mu \times F(x) = \lim_{n \to \infty} F^n(0) \).
  (compute by iteration)

---

Computing the Response Time

\[ R_i = C_i + I_i \quad I_i = \sum_{j=1}^{i-1} \left( R_j / T_j \right) C_j \]

\[ R_i = C_i + \frac{1}{\sum_{j=1}^{i-1} \left( R_j / T_j \right)} C_j \]

---

DM: Schedulability test

- For all \( i \), compute the response time \( R_i = \mu \times F(x) \) by iteration.
- Check that \( R_i \leq D_i \).
Note: when computing the k-th estimate \( R_i^k \) of \( R_i \), we have that either \( R_i^k \leq R_i^{k-1} \), or that \( R_i^k - R_i^{k-1} \geq C_{\min} \), where \( C_{\min} = \min_{1 \leq j \leq n} C_j \).

---

Computing the Response Time

\[ R_i = C_i + I_i \quad I_i = \sum_{j=1}^{i-1} \left( R_j / T_j \right) C_j \]

\[ R_i = C_i + \frac{1}{\sum_{j=1}^{i-1} \left( R_j / T_j \right)} C_j \]

This equation in \( R_i \) has many fixpoints; we want the least fixpoint.

---

EDF, for deadlines \( \leq \) periods

- When the deadline is shorter than the period, we can also use EDF.
- As usual, EDF turns out to be better than DM (similarly to EDF vs. RM when the deadlines are equal to the periods). The drawback of EDF is that it needs priorities to be changed dynamically.
EDF, for deadlines ≤ periods

- \( C_p(0,L) \): the amount of processing that is requested in \([0,L]\), and that must be completed (has deadline) before \( L \).
- \( C_p(0,L) = \sum_{i=1}^{n} \left[ \frac{L + T_i - D_i}{T_i} \right] C_i \)

EDF Schedulability

**Theorem:** A set of periodic tasks is schedulable by EDF iff, for all \( L \geq 0 \):

\[ L \geq C_p(0,L) \]

**Proof:** the theorem is proved by showing that the above is equivalent to the formulation based on utilization we showed before.

EDF Schedulability: Example

- \( J_1 \): (\( C_j = 2 \), \( T_j = 6 \) , \( D_j = 5 \))
- \( J_2 \): (\( C_j = 2 \), \( T_j = 8 \) , \( D_j = 4 \))
- \( J_3 \): (\( C_j = 4 \), \( T_j = 12 \) , \( D_j = 8 \))
- Hyperperiod: \( H = \text{mcm}(6,8,12) = 24 \).
- Deadlines ≤ \( H \):
  - 4 \( (J_3) \), 5 \( (J_2) \), 8 \( (J_3) \), 11 \( (J_2) \), 12 \( (J_3) \), 17 \( (J_2) \), 20 \( (J_3 \) and \( J_3) \), 23 \( (J_3) \).

EDF Schedulability: Example

- \( G(0,4) = C_j = 2 \leq 2 \)
- \( G(0,5) = G(0,4) + C_j = 4 \leq 5 \)
- \( G(0,8) = G(0,5) + C_j = 8 \leq 8 \)
- \( G(0,11) = G(0,8) + C_j = 10 \leq 11 \)
- \( G(0,12) = G(0,11) + C_j = 12 \leq 12 \)
- \( G(0,17) = G(0,12) + C_j = 14 \leq 17 \)
- \( G(0,20) = G(0,17) + C_j = 20 \leq 20 \)
- \( G(0,23) = G(0,20) + C_j = 22 \leq 23 \)
- Schedulable!

EDF schedulability test

- Note that we need to check that \( L \geq C_p(0,L) \) only for values of \( L \) that:
  - correspond to some deadline (since that’s where \( C_p \) may increase)
  - are smaller than the hyperperiod
    \[ H = \prod_{i=1}^{n} T_i \]
  - are no larger than the busy period
    (additional optimization, see Buttazzo)
