Hello, world!

/* HelloWorld.java
 * Purpose:
 * The classic "Hello, world!" program.
 * It prints a message to the screen.
 * Author: Jane Programmer
 * as derived from Kernighan and Richie */
class HelloWorld {
   public static void main (String[] args) {
      System.out.println("Hello, world!");
   }
}

Compiling a program

- Source code - HelloWorld.java
  - viewed with an editor
  - understandable by a human
- Object code - HelloWorld.class
  - for Java, this is machine independent byte code
  - compilers for other languages produce machine code
  - this is also called the binary form or executable

Compiling

- Create HelloWorld.java with an editor
- Execute the command:
  javac HelloWorld.java
Running your Java program

- Once it compiles with no errors, type:
  ```java
  java HelloWorld
  ```
- Notice it is not `HelloWorld.class`.
- The name here must be the name found after the keyword `class` in your program's source file. In general it should be the same as the name of the file, minus the extension.

Keywords vs Identifiers

- Keywords cannot be used for any other purpose. Examples include: `class`, `int`, `public`, `static`, `void`
- Identifiers are the names for things that you get to make up. They must start with a letter and then may include digits. $ and _ (underscore) can be used but should be avoided.

Literals

These are strings of symbols that represent “literal” data values.

- `123` is an integer literal
- `1.23` is a floating point literal
- "123" is a String literal as is "class"
- but `class` is a keyword and `Class` is an identifier
Operators and punctuation

- Operators are symbols like: +, -, / (division), and * (multiply)
- Punctuation includes symbols like: ( ), { }, and ; (semicolon)

Data types and variables

- Data types - simple to complex
  - int - for integers or whole numbers
  - double - for numbers with fractional parts
  - String - for text
  - Button - a button on a GUI
  - Point - for representing points in a plane
- Variables store data in named locations
  - every variable must have a declared type

Primitive types vs Classes

- Java has eight primitive types: byte, short, int, long, float, double, char, boolean
- Primitive types have literal values and can be manipulated with built-in operators. E.g. 
  \[ 2 + 3 \]
- Class type values are created with the operator new:
  ```java
  new Button("Quit")
  ```
Declaring Variables

int count, total;
String sentence;
boolean done;
Button clickToExit;

Initializing Variables

int count = 10, total = 0;
String sentence = "Hello there.";
boolean done = false;
Button clickToExit =
    new Button("Exit");

// HelloWorld2.java - variable declarations
class HelloWorld2 {
    public static void main (String[] args) {
        String word1; variable
        String word2, sentence;

        word1 = "Hello, ";
        word2 = "world!";
        sentence = word1.concat(word2);
        System.out.println(sentence);
    }
}
// StringVsId.java
// contrast strings and identifiers
class StringVsId {
    public static void main(String[] args) {
        String hello = "Hello, world!";
        String stringVary;
        stringVary = hello;
        System.out.println(stringVary);
        stringVary = "hello";
        System.out.println(stringVary);
    }
}

User Input

• Dissect SimpleInput.java
  – tio
  – use + to break up long string literals
  – be sure an include a prompt
  – use meaningful variable names
  – * is multiplication

// SimpleInput.java-reading numbers from the keyboard
import tio.*;    // use the package tio
class SimpleInput {
    public static void main (String[] args) {
        int width, height, area;
        System.out.println("type two integers for" +
                          " the width and height of a box");
        width = Console.in.readInt();
        height = Console.in.readInt();
        area = width * height;
        System.out.print("The area is ");
        System.out.println(area);
    }
}
Calling predefined methods

- method - a group of instructions with a name. E.g. main(), println(), readInt().
- Some methods require some data values upon which to operate.
  E.g. System.out.println(width);
- These data values are called parameters.
- Parameters are passed to methods.
- Some also return a value.
  E.g. x = Math.sqrt(y);

print() and println()

System.out.println("type two integers for" +
"the width and height.");
System.out.print("type two integers for the");
System.out.println("width and height.");

Illegal
System.out.println("type two integers for the width and height.");

Inserting newlines in a string

System.out.println("One\nword\nper\nline.");

Output

One
word
per
line.
 Numeric Types

- byte - 8 bits
- short - 16 bits
- char - 16 bits (no sign)
- int - 32 bits - +/-2 billion
- long - 64 bits - 19 decimal digits
- float - 32 bits - +/-10^-45 to +/-10^38 - 7 digits
- double - 64 bits - +/-10^-324 to +/-10^308 - 15 digits

 Numbers vs Strings

- The bit pattern in the computers memory is different for "1234" and 1234.
- The computer needs to know how to interpret the bits, hence the type for variables.
- This is just like needing to know what language is being used. Does “pie” mean something good to eat (English), or foot (Spanish)?

 Integer arithmetic

- Dissect MakeChange.java
  - variable declaration
  - user input
  - simple expression
  - integer division
  - remainder or modulo
// MakeChange.java - change in dimes and pennies
import tio.*;     // use the package tio

class MakeChange {
    public static void main (String[] args) {
        int price, change, dimes, pennies;
        System.out.println("type price (0:100): ");
        price = Console.in.readInt();
        change = 100 - price;        //how much change
        dimes = change / 10;         //number of dimes
        pennies = change % 10;       //number of pennies
        System.out.print("The change is : ");
        System.out.println(dimes + " dimes " +
                            pennies + " pennies");
    }
}

Precedence and associativity

• * and / have higher precedence than + and -
  – What is the value of 7 + 5 * 3?

• For equal precedence operators, most are left associative.
  – What is the value of 100 / 5 * 2?

• Use parentheses can be used to override the normal rules. E.g. 100 / (5 * 2)
